Does Media Violence Predict Societal Violence? It Depends on What You Look at and When

Christopher J. Ferguson

Department of Psychology, Stetson University, DeLand, FL 32729, USA

This article presents 2 studies of the association of media violence rates with societal violence rates. In the first study, movie violence and homicide rates are examined across the 20th century and into the 21st (1920–2005). Throughout the mid-20th century small-to-moderate correlational relationships can be observed between movie violence and homicide rates in the United States. This trend reversed in the early and latter 20th century, with movie violence rates inversely related to homicide rates. In the second study, videogame violence consumption is examined against youth violence rates in the previous 2 decades. Videogame consumption is associated with a decline in youth violence rates. Results suggest that societal consumption of media violence is not predictive of increased societal violence rates.

Keywords: Violence, Media Violence, Movies, Homicide, Mass Media.

doi:10.1111/jcom.12129

There are probably few cultural debates that have been waged for so long as the issue of whether media violence contributes meaningfully to societal violence. Following tragic mass shooting events committed by younger shooters, many politicians point to cultural influences as a potential contributing factor (e.g., Boleik, 2012), although others dismiss media as a contributing factor (e.g., Palmer, 2013). Similar divisions are seen within the social science community. For example, some professional advocacy groups such as the American Psychological Association (APA, 2005) have released policy statements unequivocally linking media violence to societal aggression. Recently, however, a group of approximately 230 media scholars, criminologists, and psychologists wrote an open letter to the APA asking them to retire their policy statements and refrain from making such causal attributions (Consortium of Scholars, 2013). As such, no consensus among scholars exists regarding the impact of media violence.

Corresponding author: Christopher J. Ferguson; e-mail: CJFerguson1111@aol.com

1 Evidence for and against beliefs in media violence effects are parsed from multiple 1
2 sources such as psychological laboratory experiments, correlational, and longitudinal 2
3 studies. Opinions on the validity, consistency, and meaningfulness of these studies 3
4 remain mixed (e.g., Murray, 2008; Savage, 2008). Results of such studies have been 4
5 inconsistent and some scholars have suggested that the studies themselves may be 5
6 influenced by societal narratives regarding media effects (Anderson, 2008). 6
7

8 **Evidence from experiments** 8

AQ1 9 Much of the discussion of whether media violence does or does not contribute to 9
10 societal violence has focused on laboratory based studies of aggression. Most such 10
11 experiments have focused on lesser aggressive outcomes ranging from filling in the 11
12 missing letters of words through delivering nonpainful noise bursts to a consenting 12
13 opponent. These measures of aggression and their ability to inform about real-world 13
14 violence have been controversial (Kutner & Olson, 2008). Some authors have argued 14
15 that intercorrelations between these aggression measures demonstrate conceptual 15
16 utility (Anderson, Lindsay, & Bushman, 1999) although more recent reanalysis of 16
17 this work has been less sanguine (Mitchell, 2012). Other scholars have indicated that 17
18 these aggression measures are often used in an unstandardized way, with even the 18
19 same labs sometimes extracting aggression differently between studies from a single 19
20 measure (Ferguson, 2013) and that such unstandardized aggression measures can 20
21 cause spurious effect sizes (Elson, Mohseni, Breuer, Scharnow, & Quandt, 2014). 21

22 These issues of validity aside, results for media violence effects in the labora- 22
23 tory have been mixed (Savage, 2008). For both movies and videogame violence, 23
24 some studies find evidence for effects on increased aggression (e.g., Ivory & 24
25 Kaestle, 2013; Turner & Berkowitz, 1972), null effects (Ramos, Ferguson, Frail- 25
26 ing, & Romero-Ramirez, 2013; Tear & Nielson, 2013) or even reduce aggression 26
27 (Feshbach, 1961; Mueller, Donnerstein, & Hallam, 1983; Shibuya, Sakamoto, Ichori, 27
28 & Yukawa, 2008; Valadez & Ferguson, 2012). Overall, making clear, declarative state- 28
29 ments from this body of work is difficult. Other research has indicated the laboratory 29
30 exposures to violent content do not match well with real-life exposure. For instance, 30
31 Krahé et al. (2011) found evidence for small associations between exposure to media 31
32 violence in the laboratory and mild aggression tasks, but real-life exposure did not 32
33 predict aggression in the laboratory. 33

34 The degree to which laboratory studies faithfully capture the media experience is 34
35 also debatable. Many such studies provide exposure to only brief clips of media, rather 35
36 than full narrative experiences, in which violence exposure is outside of a narrative 36
37 context. The resultant aggressive behaviors are also outside a real-world context, in 37
38 which the aggression appears to be sanctioned by the researchers themselves who pro- 38
39 vide the opportunity for aggression. The close pairing of clips of media violence with 39
40 sanctioned aggression asks may also set up demand characteristics that may explain 40
41 the small effects typically seen from such studies. The degree to which such stud- 41
42 ies, regardless of their inconsistent results, can be generalized to societal aggression 42
43 remains debatable (Savage, 2008). 43

1 Societal violence 1

2 No small part of the debate on media effects has focused on concerns that the 2
 3 introduction of violent media into society in the 20th century may have precipitated 3
 4 increasing violence in society. Scholarly arguments directly linking media violence 4
 5 exposure to increases in societal violence began in the era of the 1972 U.S. Surgeon 5
 6 General's Report on television violence, became particularly prevalent during the 6
 7 1980s (e.g., Centerwall, 1989) and continued into following decades (e.g., Bushman 7
 8 & Anderson, 2001). Such arguments were arguably sustained in part by increases in 8
 9 societal violent crime beginning in the 1960s and remaining through 1993 (Federal 9
 10 Bureau of Investigation, 1951–2012). This crime wave arguably gave a sense of 10
 11 urgency to media effects theories. 11

12 To illustrate more closely how such societal data has been used, whether correctly 12
 13 or incorrectly, to support purported links between media and societal violence, the 13
 14 scholarship of Centerwall (1989) may be considered. Centerwall's analysis compared 14
 15 homicide rates in the United States and Canada with those in South Africa, where 15
 16 television was introduced in 1975. Centerwall concluded that violence rates in South 16
 17 Africa rose following the introduction of television, mirroring the alleged effect in the 17
 18 United States. Canadian violence rates also appeared to rise following the introduc- 18
 19 tion of television although not nearly as high. A further study in Canada claimed that 19
 20 aggression rates among children rose in several small towns following the introduc- 20
 21 tion of television (Williams & Handford, 1986). 21

22 A follow-up analysis on data from four other countries; France, Germany, Italy, 22
 23 and Japan noted no relationship between the introduction of television and violent 23
 24 crime rates in those countries (Zimring & Hawkins, 1997). One naturalistic study 24
 25 examined aggression in school children after television was introduced to the iso- 25
 26 lated island of St. Helena in the South Atlantic (Charlton, Gunter, & Coles, 1998). 26
 27 Researchers examined the playground behavior of children for aggressive behaviors 27
 28 before television was introduced and for several years afterward. Results indicated 28
 29 that the introduction of television had no effect on childhood aggression. 29

30 30

31 The present research 31

32 Although much of the research on media violence concerns itself with relatively minor 32
 33 acts of aggression or competitiveness that arguably are not of societal concern (see 33
 34 *Brown v EMA*, 2011) most debates among politicians and the general public focus 34
 35 on the influence of violent media on societal violence. Examining such associations 35
 36 can help document whether media violence rates are predictive of or associated with 36
 37 fluctuations in societal violence rates. Although correlational by nature, the existence 37
 38 of co-occurring patterns would lend credence to theories linking media and societal 38
 39 violence, whereas discordant patterns would constitute a challenge to such theories, 39
 40 at least on the level of societal violence. Although many factors influence societal vio- 40
 41 lence and small influence of media may be subsumed under larger societal influence, 41
 42 the absence of a correlation would argue that, at very least, other factors are primary 42
 43 compared to media in the production of societal violence. 43

1 Debates about media violence ultimately focus on macrolevel effects, whether 1
2 media violence contributes to societal violence, yet much of the evidence is focused 2
3 on microlevel individual studies with controversial measures of minor aggression. 3
4 This is a phenomenon Farley (2012) has characterized as attempting to answer 4
5 “big V” questions using “little v” research. By actually examining the “big V” out- 5
6 comes related to societal violence, this can provide perspective of the impact of 6
7 media on macrolevel variables. Such a study is a large-scale macrolevel correlational 7
8 study. However, macrolevel variables have their weaknesses. Media exposure is not 8
9 recorded at the macrolevel and must be estimated through consumption rates. Such 9
10 estimates typically reflect audience preferences at given points in time. Thus, they one 10
11 important piece of a puzzle about media effects that should be considered in tandem. 11

12 An example regarding the importance of macrolevel variables comes from the Cul- 12
13 tural Indicators project that focused on the collection of aggregate data on television 13
14 content coupled with a concurrent temporal assessment of viewer attitudes, beliefs, 14
15 and norms (Gerbner & Gross, 1976). This approach demonstrate a method for 15
16 examining macrolevel trends in both patterns of television programming and changes 16
17 in societal beliefs in order to examine for patterns in these two. The Cultural Indi- 17
18 cators project ultimately compiled data on over 3,000 shows and explored relation- 18
19 ships between content in these shows and societal beliefs (Signorielli, Gerbner, & 19
20 Morgan, 1995). Data from the Cultural Indicators project was used to make infer- 20
21 ences regarding the potential impact of television programming on issues related to 21
22 fear of crime, alienation and insecurity, and other aspects of social reality. The Cul- 22
23 tural Indicators project approach parallels considering macrolevel variables related to 23
24 media consumption and crime for the issue of media violence effects. 24

25 Some evidence has suggested that movie violence has increased over several previ- 25
26 ous decades (Shipley & Cavender, 2001), although long-term trends remain yet to be 26
27 examined. This article seeks to address this gap in two studies, one examining movie 27
28 violence and societal violence trends across the majority of the 20th century, the sec- 28
29 ond examining videogame violence and youth violence trends across the previous 29
30 decades. 30

31 32 **Study 1** 32

33 34 In the first study, associative relationships between movie violence and homicide rates 34
35 in the United States across the 20th century were examined. 35
36 36

37 **Methods** 37

38 *Movie violence* 38

39 In order to examine movie violence trends across the 20th century, top-grossing 39
40 movies were selected from every fifth year starting with 1920 and ending 2005. 40
41 Five-year intervals were used as reviewing top-grossing movies from every year 41
42 inclusive would have involved thousands of person-hours and because available 42
43 research suggests that violence rates in media typically do not change dramatically 43

1 across intervals of several years (Smith et al., 1998). As indicated through content 1
2 analysis from the National Television Violence Study, violent content is relatively 2
3 stable across small units of time spanning several years (see also Signorielli, 2003). 3
4 For each year, the top five grossing movies were selected for rating. If a movie was not 4
5 available due to being out of print, the next highest-grossing movie was selected in its 5
6 stead. High-grossing movies were selected as being most likely representative of the 6
7 general public's diet of movie violence, given the wide viewership of these movies. 7
8 Five exemplars were included for each year to get a general rating of movie violence 8
9 for that year that would be less likely to be spurious due to a single, particularly violent 9
10 movie. A total of 90 films were included in the current analysis. Seven films (*Over the* 10
11 *Hill*, *His People*, *The Plastic Age*, *Pollyanna*, *The Rogue Song*, *The Golem*, *East Lynne*), 11
12 all from 1920–1930, were initially identified for inclusion but proved difficult to 12
13 locate and were replaced with films from the same or adjacent year (*Mata Hari*, *Seven* 13
14 *Chances*, *The Lost World*, *Phantom of the Opera*, *Last of the Mohicans*, *Within Our* 14
15 *Gates*, *The Kid*). A full list of films included in the analysis is available upon request. 15

16 Each movie was rated for violent content using an interval rating approach. 16
17 Trained raters viewed each movie and recorded at each 1-min interval whether any 17
18 violent acts had occurred during the previous minute. Interval rating was used due 18
19 to difficulty in interpreting strict count-based rating. For instance, a movie might 19
20 include a brief war scene with hundreds of simultaneous acts of violence in a short 20
21 period, yet be relatively nonviolent otherwise. It did not appear that such a movie 21
22 should be considered more violent due to a strict count than a movie that included 22
23 individual acts of violence throughout. Violence was defined for the purpose of rat- 23
24 ings as “Any act (e.g., hitting, kicking, shoving, slapping, shooting, stabbing) causing 24
25 intentional harm, injury or death, including war scenes, torture, rape, strangulation, 25
26 or assault.” Raters were trained to include comedic violence as well as graphic vio- 26
27 lence and also violence toward nonhuman animals or other characters, particularly 27
28 given the popularity of some animated films, as well as human-on-human violence. 28
29 A violence quotient was calculated by dividing the number of minutes in which a 29
30 violent act occurred by the total number of minutes in the movie. 30

31 Graphicness of the violence was also rated for each movie. This consisted of six 31
32 likert-scale questions regarding the degree to which the movie had, overall, depicted 32
33 (a) visible blood or gore, (b) depicted maiming or decapitation, (c) displayed internal 33
34 organs or body parts in the context of violence, (d) showed other graphic wounds, (e) 34
35 depicted victims of violence in visible pain or (f) included scenes of rape or sexual 35
36 abuse. A summed score of these items constituted graphic violence. 36

37 To calculate interrater reliability, a subset (59%) of the movies was independently 37
38 rated by two raters. Interrater reliability was calculated using the Krippendorff 38
39 formula (Hayes & Krippendorff, 2007). Interrater reliability was high at $r_k = .80$ for 39
40 movie violence frequency and $.85$ for graphicness. Bootstrapping with 1,000 samples 40
41 revealed a 95% confidence interval of $.58$ to $.97$ for movie violence and $.77$ to $.91$ 41
42 for graphic violence. Assignment of raters to movies was random and was evenly 42
43 distributed among four raters. It was intended that at least half (50%) of movies 43

1 would be rated by two raters to establish interrater reliability and the current analysis
2 exceed this slightly.

3 *Homicide rates*

4 Homicide (specifically murder and nonnegligent manslaughter) rates were chosen as
5 the outcome indices in the perception that, among violent crimes, these would be least
6 likely to shift due to definitional changes or enforcement changes that could introduce
7 history confounds over large spans of time (LaFree, 2005; O'Brien, 2003). Homicide
8 rates were obtained from Uniform Crime Reports data (Federal Bureau of Investiga-
9 tion, 1951–2012; United States Department of Justice, 2005, 2006, 2009a).¹

11 *Median household income*

12 Median household income (MHI) was considered as a control variable for the dates
13 available. The U.S. Census Bureau (2013) began keeping and tracking such data, infla-
14 tion adjusted, beginning in the late 1960s. Thus, data was available for the years 1970
15 and beyond for this study.

17 *Policing*

18 At the request of the current investigator the U.S. Department of Justice compiled
19 figures on the number of police officers employed each year beginning in 1970
20 (Carey, personal communication, 2007). The number of police officers employed as
21 reported to the U.S. Department of Justice by police departments, was divided by the
22 total U.S. population in order to adjust for population increases. This ratio remained
23 stable between .17 and .19 through the 1970s and 1980s and began to increase slightly
24 between .20 and .21 beginning in the 1990s and 2000s. Like MHI, this variable was
25 used as a control variable for later years (1970 and beyond) for which data was
26 available.

28 *Population density*

29 Population density data was obtained from the U.S. Census Bureau (2002, 2010a,
30 2010b). Population density is reported for each 10-year block. Population density for
31 years ending in “5” (e.g., 1945) was estimated using the average of the values reported
32 for “0” years reported before and after (e.g., the average of population density reported
33 for 1940 and 1950).

34 *Youth population*

35 The proportion of youth under the age of 24 was also included as a control variable.
36 These data was also obtained from the U.S. Census Bureau from the sources identified
37 above. Data on years ending in “5” were also estimated using the same procedure as
38 described for population density.

40 *Real gross domestic produce per capita (GDP)*

41 A final control variable was the real gross domestic product of the United States,
42 adjusted for inflation and population. This is valuable as one economic indicator and
43 these data are available from the Bureau of Labor Statistics (2012) beginning for 1960.

1 *Statistical analyses* 1

2 Main statistical analyses consisted of bivariate correlations between movie violence 2
 3 and graphicness levels and societal homicide rates. Partial correlations were also 3
 4 calculated with MHI, policing, population density, youth population and real GDP 4
 5 as control variables. Time series analysis will also be examined to analyze trends 5
 6 with autocorrelations in the series removed. Given the relatively low number of years 6
 7 involved, interpretation of correlation coefficients focused on effect size (as indicated 7
 8 by the r value) rather than statistical significance (Cohen, 1988). 8

9 Control variables selected above were selected for their theoretical links with 9
 10 crime trends. Explanations for crime trends continue to be debated among crimi- 10
 11 nologists, although leading theories involve variables such as policing (Schneider, 11
 12 Pilon, Horrobin, & Sideris, 2000) or economic and demographic changes over time 12
 13 (Bukenya, 2005). Thus, controlling for related variables may help to identify history 13
 14 effects that may have created spurious correlations regarding movie violence and 14
 15 crime trends. 15

16 **Results** 16

17 Examining trends in movie violence suggests that frequency of violence in movies 17
 18 has followed a rough U-pattern across the 20th century. Violence in movies was quite 18
 19 common in the 1920s, rapidly diminishing, only to return in the latter part of the 19
 20 20th century, beginning in the 1960s, but particularly in the 1980s. This diminishing 20
 21 of violence in movies appears to correspond to the Motion Picture Production Code 21
 22 or Hays Code of 1930 that was a code of voluntary censorship by the movie industry 22
 23 designed to offset criticisms of violence and other objectionable content in movies. 23
 24 By contrast, graphicness of violent content shows a more clearly increasing pattern 24
 25 across the 20th century, particularly beginning in the 1950s (Figure 1). 25
 26

AQ4

27 Bivariate correlations suggest a moderate relationship between frequency of 27
 28 movie violence and homicide rates $r = .33$ ($df = 17$, $p = .19$), although the relation- 28
 29 ship between graphic violence and homicide rates was small $r = .13$ ($df = 17$, $p = .60$). 29
 30 Controlling for MHI, proportion of youth and population density did not reduce 30
 31 these correlations. Correlations between violence frequency and homicide remained 31
 32 at $r = .35$, $.42$ and $.37$ respectively (ps ranged $.09$ to $.45$), for these variables controlled, 32
 33 whereas correlations between movie graphicness and homicide were at $r = -.10$, 33
 34 $.38$ and $.30$ respectively (ps ranged $.13$ to $.83$), with these variables controlled. The 34
 35 relationship between movie graphicness and homicide demonstrated greater vari- 35
 36 ability depending upon which control variables were employed, than did violence 36
 37 frequency. However, controlling for policing and real GDP did. With policing con- 37
 38 trolled, correlations between media violence frequency and societal homicide rates 38
 39 dropped to $r = .06$ ($p = .89$) and $r = -.22$ ($p = .64$) for graphic violence. Controlling 39
 40 for real GDP dropped the correlation between movie violence and homicide and for 40
 41 graphic violence and homicide both to $r = -.04$. 41

42 Time series analysis was conducted using ARIMA models in SPSS. Autocorrela- 42
 43 tions in the trends were removed using the Box-Jenkins approach. Using this approach 43

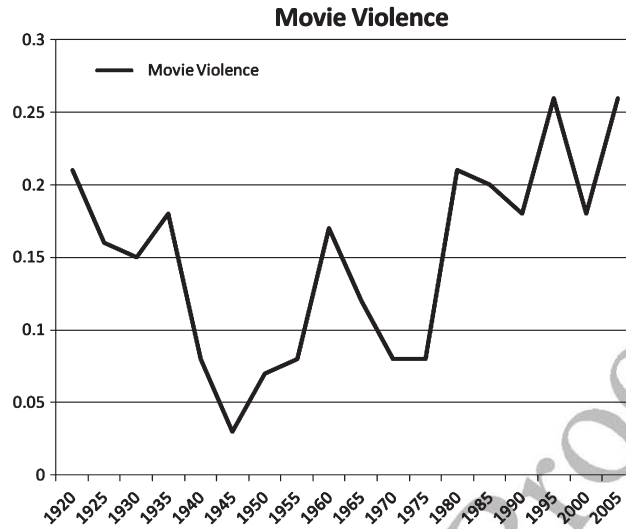

Figure 1 Trends in movie violence across the 20th century.

creates residuals that are free of autocorrelations (Warner, 1998). The procedure can help in the removal of spurious trends. However, time series analysis is best run with observations greater than 50 and the current observations are fewer than these so results should be interpreted with caution. With the model for the prediction of movie violence frequency and graphicness considered as predictors of homicide, and controlling for autocorrelations, the effect size for the relationship between movie violence and homicide dropped to $r = .18$ and for graphicness $r = .08$. After two autoregressive parameters were added to the model Ljung-Box Q tests for white noise residuals revealed that when homicide was predicted movie violence (Ljung-Box Q at lag 10 = 11.52, $p = .31$) or graphic violence (Ljung-Box Q at lag 10 = 10.23, $p = .42$) there were nonsignificant autocorrelations among the residuals, with effect sizes returning to $r = .30$ and $.13$ respectively. Thus, time series analyses did not differ significantly from the basic correlations.

The relationship between movie violence and societal homicide, also appears to have been driven mainly by increases in both phenomena during the mid-20th century. When only the years from 1970 on are considered, the relationship reverses in trend with homicide rates correlated $r = -.28$ ($df = 8$, $p = .50$) with frequency of movie violence and a strong $r = -.61$ ($df = 17$, $p = .11$) with movie graphicness. For the years prior to 1940, movie violence demonstrated an almost perfect inverse relationship with societal violence with the two variables correlated $r = -.98$. Figure 2 presents the long-term trends for frequency of movie violence and homicides across the 20th century. As can be seen, these two phenomena were divergent in the 1920s, then largely tracked each other through the midcentury before diverging once again approximately around 1990 with this divergence continuing into the 21st century.

AQ5

Figure 2 Trends in movie violence and homicide (murder and nonnegligent manslaughter) across the 20th century.

Discussion

Graphic elements of movie violence have been on a steady liberalizing trend, particularly in the latter half of the 20th century. Interestingly, this trend toward more graphic violent content is not correlated with societal violence. The frequency of violence in movies has demonstrated a U-curve, with early movies from the 1920s being fairly violent before the imposition of the self-censorship of the Hays Code in 1930 resulting in a significant decrease in movie violence. Movie violence then began to increase once again in the latter 20th century. This is consistent with a previous analysis by Shipley and Cavender (2001).

Although graphic violence did not correlate with societal violence, frequency of violence in movies did correlate with societal violence in the form of homicides. This correlation was fairly small and driven mainly by concordance during the mid-20th century. By the latter 20th century this concordance trend had reversed itself with movie violence associated with *reduced* societal violence in the form of homicides. Further, the correlation between movie and societal violence was reduced when policing or real GDP were controlled.

Taken together these data suggest that perceived correlations between movie and societal violence were associated with a chance concordance during the mid-20th century. Given that these phenomena were not in concordance in either the early or latter 20th century, it appears that efforts to establish causal connections between movie and societal violence based on a select set of decades were an ecological fallacy.

1 Study 2

2 In the first study, frequency of movie violence correlated with societal violence only
3 in the mid-20th century, not the early or latter portions of the century. Although this
4 would initially question the notion that societal and media violence rates are mean-
5 ingfully linked, it could be reasonably argued that some *other* phenomena may be
6 masking relationships between media and societal violence rates. For instance, the
7 United States has seen a considerable increase in per capita incarceration in recent
8 decades (United States Department of Justice, 2009b). It could be argued that media
9 violence does have an effect on societal violence, but that by incarcerating such a high
10 percentage of antisocial individuals, societal violence is driven back down once again.
11 This argument has flaws. For instance, such an argument does not explain the dis-
12 crepancy between media and societal violence rates in the 1920s and 1930s. Nor does
13 it explain the observation that other countries (e.g., The Netherlands, Japan, South
14 Korea) with high violent media consumption and relatively low incarceration rates
15 are among the least violent (Sternheimer, 2013).
16

17 One way to examine this issue is to explore whether youth violence, typically
18 occurring at ages prior to incarceration, correlated with the introduction of new
19 media. Youth are often conceptualized as being particularly vulnerable to media
20 effects, relative to older populations. Youth are also most likely to consume new
21 media such as videogames (Aarsand, 2007). Violence rates among youth are con-
22 sistent across youth age categories (childstats.gov, 2013) which is one means of
23 addressing the potential contaminating effects of incarceration rates. Indeed, previ-
24 ous analyses have specifically ruled out incapacitation due to incarceration as a factor
25 in declining youth violence rates (Stahlkopf, Males, & Macallair, 2010). If media
26 violence is a precursor to societal violence the introduction of violent videogames in
27 the United States should be expected to precipitate increased youth violence rates,
28 particularly given that other forms of media such as television and movies have not
29 abated in regard to violence levels. This was effectively the argument used during
30 previous decades of television violence research (e.g., Centerwall, 1989). Thus, this
31 second study is designed to test the hypothesis that societal consumption of violent
32 videogames is associated with societal rates of youth violence.
33

34 Methods

35 *Videogame violence*

36 Data on consumption of videogames in terms of units sold is available from The
37 Entertainment Software Administration (2013) which is a trade group representing
38 the videogame industry. Their data are provided through the NPD group, an inde-
39 pendent provider of consumer and retail information. Videogames data in terms of
40 units sold was used in order to control for inflation influences on dollar sales figures.
41 These data included figures for sales of physical discs and downloads, which prevents
42 underestimation of videogame sales as delivery of games moves increasingly away
43 from “brick and mortar” outlets. However, it should be noted that these figures do

1 not include games provided through other media such as cell phones, social media, 1
 2 or noncommercial games provided online. 2

3 General videogame sales figures in units sold do not distinguish between violent 3
 4 and nonviolent games. To get an estimate of violent game consumption specifically, 4
 5 top five selling videogames for each year were obtained from the Internet Movie 5
 6 Database (imdb.com) which tracks videogames and other media in addition to 6
 7 movies. The IMDB includes a wide array of information including sales data for 7
 8 movies and videogames. The IMDB includes wide-release commercial videogames 8
 9 including those released on nontraditional platforms such as apps, but does not 9
 10 necessarily include all noncommercial or serious videogames. However, videogames 10
 11 likely to see most widespread use are included in the IMDB data. These popular 11
 12 games were rated on a scale of 1 to 5 for violent content in accordance with the 12
 13 rating provided to them by the Entertainment Software Ratings Board (ESRB) which 13
 14 rates games as EC for early childhood, E for Everyone, E10+ for ages 10 and over, 14
 15 T for Teen, M for Mature (there were no games in the current sample rated in the 15
 16 higher AO category). The use of ESRB ratings as an estimate of violent content has 16
 17 been found to be one of the most reliable and valid estimates of violent content in 17
 18 past research (Kutner & Olson, 2008). Videogame violence consumption each year 18
 19 was created by summing the ESRB ratings for five most popular videogames and 19
 20 multiplying this number by the total units of videogames sold. This product estimated 20
 21 societal exposure to violent videogames by weighting the overall consumption of 21
 22 videogames in units sold by the violent content of the most popular games. 22

23 This approach differs somewhat from the content-analysis approach of the first 23
 24 study. With movies a content-analysis approach was necessary as no reliable, stan- 24
 25 dardized approach for rating movies existed until the MPAA system of the 1960s. 25
 26 With videogames the ratings-based approach has been found to be reliable and valid, 26
 27 and was present for all included years of this study. As such, a ratings-based system 27
 28 was employed. 28

29
 30 *Youth violence* 30

31 Official government per capita rates of youth (12–17) violence were obtained from 31
 32 the government website childstats.org (2013) which maintains statistical data related 32
 33 to children's behavioral and medical health and tracks these data over time. Data on 33
 34 youth violence for the childstats.org site come from the National Crime Victimization 34
 35 Survey. These rates include reported juvenile offenders of serious violent crimes as 35
 36 reported by victims, as well as perpetrator of homicides as reported by police depart- 36
 37 ments in the age range of 12–17 years. Crimes involved include homicides, rape, 37
 38 aggravated assault, and robbery (stealing under threat or use of violence). 38

39
 40 *Statistical analyses* 40

41 Simple bivariate correlations were assessed between videogame violence exposure in 41
 42 society and youth violence. This study includes the years from 1996 through 2011, the 42
 43 only years in which both sets of data were available. 43

Figure 3 Societal videogame violence consumption and societal youth violence, 1996–2011.

Results

Violent videogames were among the most popular in most years. Summed scores of the five videogames popular each year had a potential range of 5 (if all popular games were children's games) through 25 (if all popular games were rated M for mature). The mean sum score across years was 21.4 ($SD = 2.99$), indicating a high proportion of games rated T for teen or M for Mature, most of which contain significant violence. Of the 16 years considered in this analysis, all but 4 had average sum scores of 20 or above (again, equivalent to rating T or above). Eight of the 16 were summed at 23 or above, indicating a high proportion of M for Mature games.

The trend lines between videogame violence in society and societal youth violence are presented in Figure 3. As can be seen, videogame violence consumption in society is *inversely* related to societal youth violence. The bivariate correlation between these two phenomena is $r = -.85$ ($df = 15$, $p = .001$). Regarding time series analysis Ljung-Box Q tests for white noise residuals revealed that when this youth violence was predicted from videogame sales (Ljung-Box Q at lag 10 = 10.24, $p = .42$) there were nonsignificant autocorrelations among the residuals.

Discussion

Data comparing videogame violence consumption to youth violence in society demonstrates an inverse relationship, at least for the years 1996 through 2011 when both sets of data were available. This relationship appears to be remarkably strong.

1 However, it is important to point out that this is not an indication of causality. 1
2 Indeed, as seen in Study 1, media trends and societal trends can track for a time, in 2
3 one direction or another, but often reverse. In this study, data were available for only 3
4 a limited number of years and it is likely the trend would vanish or reverse with a 4
5 longer time span with which to work. 5

6 However, these data conflict with the view that the introduction of videogame 6
7 violence in society should have precipitated greater or at least a sustained high level 7
8 of youth violence. Instead, youth violence dropped precipitously, despite maintain- 8
9 ing very high levels of media violence in society with the introduction of videogames. 9
10 These data are particularly important given that, unlike for the homicide data in Study 10
11 1, this cannot be explained through an incapacitation effect due to incarceration rates 11
12 (Stahlkopf et al., 2010). Evidence from societal data does not support claims of dra- 12
13 matic videogame violence effects on violence among youth. 13

14 15 **General discussion** 15 16

17 The issue of whether media violence contributes to societal violence has been a con- 17
18 tentious one across recent decades. Numerous experimental, correlational, and longi- 18
19 tudinal studies have failed to provide a consistent answer one way or another regard- 19
20 ing this question (Adachi & Willoughby, 2012; Ivory, 2013). In the past some scholars 20
21 have argued that increases in media violence may have explained societal violence 21
22 trends (e.g., Bushman & Anderson, 2001; Centerwall, 1989). However, relatively little 22
23 data has been produced to examine this claim. 23

24 Two studies examined the impact of movie (Study 1) and videogame (Study 2) 24
25 violence on societal violence related to homicides and youth violence respectively. 25
26 Neither study provided evidence for the belief that media violence and societal 26
27 violence are meaningfully correlated. Study 1, in particular, demonstrated how such 27
28 beliefs may come into being. Movie violence displayed differing patterns of correlation 28
29 depending upon the time frame examined. Both early and late in the 20th century, 29
30 movie violence was associated with decreased societal violence. However, during the 30
31 mid-20th century movie violence and societal violence trends appeared to coincide. 31
32 So long as scholars and policy makers took a relatively short view, examining only 32
33 midcentury figures, it is understandable that many considered movie violence and 33
34 societal homicides to be correlated. However, a longer view, including both earlier and 34
35 later decades reveal this to have been a temporary trend, and thus an ecological fallacy. 35

36 In Study 2, youth violence rates were considered given that trends in youth 36
37 violence cannot be explained as due to incapacitation incarceration effects (Stahlkopf 37
38 et al., 2010). Results from Study 2 lent further credence to skepticism regarding an 38
39 association between societal violence and media violence. In this case, videogame 39
40 violence consumption rates were strongly associated with *reduced* youth violence 40
41 rates that cannot be explained as an incapacitation effect. However, particularly 41
42 given the comparatively short time frame involved, this negative correlation between 42
43 videogame violence and youth violence is just as likely to be an ecological fallacy as 43

1 were purported links between television and movie violence in the mid-20th century 1
2 and increasing violence rates in society at that time. 2

3 4 **Theoretical implications** 4

5 Results from the two studies suggest that socialization models of media violence may 5
6 be inadequate to our understanding of the interaction between media and consumer 6
7 behavior at least in regard to serious violence. Indeed for some time, scholars have 7
8 argued that such models may be inadequate (Freedman, 1984; Gauntlett, 2005). Cur- 8
9 rent “hypodermic needle” theories of mass media effects on behavior ultimately may 9
10 imply simplistic modeling of behavior, focused too heavily on the development of 10
11 automatic cognitive scripts (Ferguson & Dyck, 2012). Such theoretical models may, 11
12 effectively, remove the user from the media experience except as a passive “victim” 12
13 of a powerful, influential media. Although some scholars claim that empirical evi- 13
14 dence supporting hypodermic needle approaches is considerable (Gentile, Saleem, & 14
15 Anderson, 2007), others have argued that such evidence is actually weak and the time 15
16 has come to reconsider communication theory as it applies to media effects (Lang, 16
17 2013). 17

18 By contrast, several models have been proposed to suggest that the interac- 18
19 tion between media and consumers may be motivationally driven rather than 19
20 content-driven, with idiosyncratic effects seen between consumers depending upon 20
21 their motivations (e.g., Przybylski, Rigby, & Ryan, 2010; Sherry, Lucas, Greenberg, & 21
22 Lachlan, 2006). These theories such as Uses and Gratifications (Sherry et al., 2006) 22
23 and Self-Determination Theory (Przybylski et al., 2010) posit media as fulfilling 23
24 pre-existing motivational structures. Thus, a particular form of media may have 24
25 very different influences depending more on what individual consumers seek to 25
26 achieve rather than on content specifically. Indeed, some early work has suggested 26
27 exactly this, that individual behavioral outcomes due to media exposure can be quite 27
28 idiosyncratic and unpredictable (e.g., Unsworth, Devilly, & Ward, 2007). 28

29 In effect, understanding the absence of discernible effects for mass media con- 29
30 sumption on societal outcomes may not necessitate believing that media has no sig- 30
31 nificant impact on consumers. Rather, adoption of a limited effects model in which 31
32 user motivations rather than content drive media experiences may help us understand 32
33 how media can have influences, yet those influences result in only limited aggregate 33
34 net impact in society. User motivations determine what users watch and what influ- 34
35 ences they hope to experience from media. Thus content, even objectionable content 35
36 such as graphic violence, may have very different influences from one user to another. 36
37 This was, for instance, the results of Unsworth et al. (2007) who found that videogame 37
38 violence calmed some youth, agitated others, and had little influence at all on the 38
39 majority. Although a limited effects approach, based on Uses and Gratifications or 39
40 Self-Determination Theory may be less prone to dramatic headlines linking media 40
41 violence to societal violence, adoption of such theoretical models may lead to a more 41
42 sophisticated understanding of the interaction between consumers and mass media 42
43 than has been possible with moralistic content-based approaches. 43

1 From a limited effects approach we can begin to see that the media experience 1
2 would be far more contextual than assumed under hypodermic needle approaches 2
3 that have traditionally dominated the field. From such an experience the media 3
4 experience can be formulated as a multistep process. The initial step in such a 4
5 process would involve user motivations, and personality factors that shape media 5
6 selection. Prioritizing the media user as a shaper of their own media experience is 6
7 central to such an approach. Media exposure is, thus, a selection based experience, 7
8 individually tailored by users based on their motivations. Based on such motiva- 8
9 tions, individual users can be expected to process media differently as well. That 9
10 is to say, the influence a particular form of media may have on individual users 10
11 may differ widely from one user to the next based on their motivations and how 11
12 they process and react to the media in question. This is, again, quite different in 12
13 perspective from hypodermic needle approaches that assume fairly uniform out- 13
14 comes, differing only in magnitude from one user to the next. Further, it can be 14
15 anticipated that users will understand that the media experience differs from real-life 15
16 and it should not be assumed that ready transfer occurs from media to real-life 16
17 behavior (Bennerstedt, Ivarsson, & Linderoth, 2012). Lastly, under such an approach, 17
18 given that behavioral outcomes occur in the real-world, it would be anticipated 18
19 that real-world controls remain primary in shaping even behavior that may be 19
20 influenced by media. That is to say, it should not be assumed that the reward struc- 20
21 tures of the media experience can override reward and punishment structures from 21
22 real-life. 22

23 Understanding motivational structures for media use can be instrumental in 23
24 understanding why users come to different forms of media for different purposes. 24
25 For instance, Weaver, Zelenkauskaitė, and Samson (2012) found that Youtube video 25
26 content is less violent than traditional television, even for television clips uploaded 26
27 to Youtube. This may be because users associate social media such as Youtube with 27
28 a different type of experience than traditional media and are drawn to outlets like 28
29 Youtube less to be entertained through traditional narrative format, but through 29
30 shorter, amusing clips, through information, or for social connection. In this sense, 30
31 a different set of motivations is instrumental in shaping two areas of media into two 31
32 very different landscapes. 32

33 Other theoretical approaches such as Routine Activities Theory (Cohen & 33
34 Felson, 1980) suggest that, whatever the impact of media violence on mood or 34
35 motivation, merely engaging in the behavior of watching violent movies or playing 35
36 violent videogames occupies time and, thus, removes individuals from oppor- 36
37 tunities to offend, thus reducing criminal violence. For example, several studies 37
38 have suggested that the release of violent movies (Dahl & DellaVigna, 2009) and 38
39 videogames (Markey, Markey, & French, in press) are associated with reductions in 39
40 societal violence rather than increases, lending support to Routine Activities Theory. 40
41 Future studies may wish to consider the ways in which new technologies, even with 41
42 offensive content, may provide routine activities or opportunities for friendship and 42
43 socialization that may take away from opportunities for antisocial behavior. 43

1 These results also highlight the risks of overextending the results from a particular
2 methodology, when outcomes from other methodologies may produce conflicting
3 results. In this case, the results from laboratory studies of aggression have been
4 arguably overextended into questions about societal violence (Farley, 2012) in many
5 cases ignoring inconsistencies in this set of data to do so. Even if we were to assume
6 that laboratory studies of aggression produced consistent results, the difficulty in
7 establishing links between societal media consumption and societal violence indi-
8 cate that far greater caution need be applied in the generalization of laboratory
9 phenomena to real-world behavior. This is, of course, true for all areas of research.
10 Although the errors of the media violence debate highlight the need for greater cau-
11 tion throughout media and communication studies, it is not unreasonable to suspect
12 that the overextension of research findings beyond the limits of the data are more the
13 norm than the exception. All fields of communication and psychology would do well
14 to adopt a culture of greater conservatism and caution in communicating research
15 findings. The alternative is damage to scientific credibility of our fields (Hall, Day, &
16 Hall, 2011).

18 Policy implications

19 As a practical issue, within the United States, the *Brown v. EMA* decision of 2011,
20 wherein the majority decision found both that violent media (specifically videogames)
21 enjoyed First Amendment protections and that research on the “harm” of such media
22 was not persuasive, has made regulation of violent media unlikely. Arguably, a more
23 important question is whether attention to the media violence debate can actually be
24 damaging in regard to society’s attention to more pressing issues influencing violence
25 such as poverty or mental health. Indeed, following the Sandy Hook shooting of 2012,
26 the National Rifle Association clearly attempted to draw links between media violence
27 and societal violence, arguably in an attempt to distract society from debates about
28 gun control. As indicated earlier, such efforts are likely abetted, if unintentionally, by
29 problematic policy statements by groups such as the American Psychological Asso-
30 ciation drawing links between media and societal violence despite much evidence to
31 the contrary.

32 As a matter of policy, consistent with the statement by the Consortium of Scholars
33 (2013) it may be best for such professional organizations to retire their policy state-
34 ments on media violence as such statements tend to be misleading and may cause
35 more harm than good. Certainly, such statements risk damaging the credibility of
36 social science (Hall et al., 2011), but they may also do damage to the extent they
37 distract society from other pressing issues. Indeed, some scholars have argued that
38 politicians and groups such as the National Rifle Association specifically use moral
39 panics over media or youth to focus attention onto culture war issues rather than
40 intractable social problems requiring great political capital and investment to solve
41 (Males, 2013). It is difficult to fully explore the inside motivations for professional
42 organizations to release such policy statements, particularly when media-based pol-
43 icy statements released by professional organizations have so often been revealed to

1 be flawed (e.g., Ferguson, 2013; Magid, 2011). It could be that such policy statements 1
2 are part of a larger system of politics and social narratives that do not well-reflect 2
3 actual science. For instance, it has been revealed that past policy statements were typ- 3
4 ically developed by specially selected researchers heavily invested in antimedia views, 4
5 with no dissenting voices (Ferguson, 2013). Such scholars typically reviewed their own 5
6 work and declared such work beyond further debate. Such review processes, which are 6
7 more the norm than the exception, should not be mistaken for careful and objective 7
8 scholarly reviews. Professional organizations may arguably do well to take a wider 8
9 view and consider the larger negative impact such policy statements can have, both 9
10 on the field (Hall et al., 2011) but also on society to the extent such policy statement 10
11 fuel moral panics (Muschert, 2007) and inadvertently act as impediments for progress 11
12 in other areas (Males, 2013). 12

13 Regarding news coverage of media violence debates, a recent article documented 13
14 that news coverage of media violence has become more skeptical in recent years 14
15 (Martins et al., 2013). The authors conclude that scholars should encourage journal- 15
16 ists to make more conclusive statements linking media violence to societal violence. 16
17 Other scholars (e.g., Gentile, 2013) have explicitly suggested that journalists should 17
18 not speak to scholars who are skeptical of links between media and societal violence, 18
19 thus appearing to endorse scientific censorship of scholars who disagree with their 19
20 personal views. However, attempts to generalize laboratory studies of aggression to 20
21 societal violence have been specifically rejected by other media scholars (e.g., Farley, 21
22 2012). Further, endorsement of scientific censorship views such as those espoused 22
23 by Gentile (2013) and less strenuously implied by Martins et al. (2013) are arguably 23
24 anathema to the foundational value of open inquiry and discourse that is critical 24
25 to scientific progress. So long as the issue of media violence is being debated in the 25
26 pages of leading journals such as *Journal of Communication* or *American Psychologist* 26
27 journalists have reason to cover those debates fairly. Arguably, given that the results 27
28 from the effects paradigm have been weak and inconsistent (Lang, 2013) it may be 28
29 time for scholars to make less rather than more conclusive statements to news media 29
30 regarding media effects on society. 30

31 32 **Limitations and future directions** 32

33 This study has several limitations that must be considered. First, all data are corre- 33
34 lational in nature and causality cannot be inferred from such data. Indeed, that is 34
35 arguably one of the conclusions of this study, the degree to which correlations between 35
36 media and societal violence, whether positive or negative, can be ecological fallacies. 36
37 A second issue with this study was that not all pieces of data such as law enforcement 37
38 personnel or mean household income were available for all years. Similarly videogame 38
39 consumption data are available only from the years 1996 and beyond. Thus, it was not 39
40 always possible to consider the interaction between multiple societal-level variables 40
41 that would have been desirable. More sophisticated designs incorporating multiple 41
42 societal-level variables would be of great value. Given that aggregate data on media 42
43 violence consumption are not available, this study used estimation procedures for 43

1 this exposure. Any such estimation procedure runs the risk of over or underiden- 1
2 tifying exposure and results should be interpreted with caution. Finally, due to the 2
3 small number of observations in these studies, results from the time series analyses 3
4 should be regarded as preliminary. 4

5 This study sought to examine whether media violence and societal violence 5
6 co-occur in a meaningful fashion that would lend credence to fears regarding media 6
7 violence influences on society. By and large societal data do not appear to support this 7
8 contention. Indeed, despite an explosion in the availability of mass media and liberal- 8
9 ization of violent content in the same, we are living in what is likely the most peaceful 9
10 epoch in human history (Pinker, 2011). Further, preliminary analyses suggest that 10
11 nations with the highest level of violent media consumption are among the most 11
12 nonviolent (Washington Post, 2012). It is difficult to say to what degree associations 12
13 that scholars made between media and societal violence in published work may have 13
14 contributed to the difficulty the field has sometimes had in accommodating newer 14
15 research and societal data. However, it may be prudent for scholars, in the future, 15
16 to be more cautious in making claims linking societal violence and media violence. 16
17 Such claims, though having political appeal, may do more damage than good to both 17
18 the field and society in the long run. 18

19 20 **Acknowledgment** 20

21 The author thanks Patrick Markey for assistance with time series analysis. 21
22 22

23 24 **Note** 24

25 1 However, some scholars have indicated the early 20th century data may have 25
26 undercounted some homicides and the adjusted estimates provided by Eckberg (1995) for 26
27 these early dates are used. 27
